Example (Are the number of 1s in xy even (0), or odd (1)?)

$$f: \mathbb{B}^n \times \mathbb{B}^n \to \mathbb{B}$$
 is precisely $(x, y) \mapsto \bigoplus xy$.

Example protocol Π :

$$P1 = parity(x)$$
.

 $P2 = parity(y) \oplus P1$

Now both Alice and Bob know f(x,y) = P2. $C(f) \le 2$ because $C(\Pi) = 2$ and Π implements f. But $C(f) \ge 2$ because f depends on x and y. Hence C(f) = 2.

Definition (Fooling Set)

If $f: \mathbb{B}^n \times \mathbb{B}^n \to \mathbb{B}$ is a function, a *fooling set* for f is a set $S \subseteq \mathbb{B}^n \times \mathbb{B}^n$ such that for some choice $b \in \mathbb{B}$ $f(S) = \{b\}$ but, for all distinct $(x,y), (x',y') \in S$, either $f(x,y') \neq b$ or $f(x',y) \neq b$

Basically, a fooling set is a group of inputs that go to the same output, but which is *brittle* to argument-swapping. In some sense these *brittle* sets lower-bound the difficulty in grouping like inputs.

With the *fooling set* method, we lower-bounded C(f). Now we'll introduce a new method that both lower- and upper-bounds C(f).

Definition (M(f))

The matrix of f, denoted M(f), is the $2^n \times 2^n$ matrix whose (x, y)th entry is the value f(x, y).

Communication Complexity

Tiling Method

With the fooling set method, we lower-bounded C(f). Now we'll introduce a new method that both lower- and upper-bounds C(f).

Definition (M(f))

The matrix of f, denoted M(f), is the $2^n \times 2^n$ matrix whose (x, y)th entry is the value f(x, y).

Example $(M(\vee))$

	00	01	10	1:
00	00	01	10	1:
01	01	01	11	1:
10	10	11	10	1:
11	11	11	11	1

- The green cells are Alice's possible inputs x.
- The blue cells are Bob's possible inputs v.
- The uncolored cells are the matrix M(f).

Reference:

NTS: $C(f) \le 16(\log_2 \chi(f))^2$. [1]

Proof.

Each stage proceeds as follows.

- Alice looks for a rectangle $M_i = X_i \times Y_i$ s.t. $x \in X_i$ and $\deg_I(i) \le 3\chi(f)/4$.
 - 1 If she finds some such rectangle then she sends *i* to Bob.
 - 1 Bob replies to indicate if $y \in M_i$.
 - 2 If so then the protocol ends because f(x, y) is the color of M_i .
 - 3 Otherwise $X := X \cap X_i$, and each rectangle $M_\alpha = X_\alpha \cap Y_\alpha$ is replaced with $(X_i \cap X_\alpha) \times Y_\alpha$.

Otherwise she replies that she found no such rectangle. In this case Bob does what Alice just attempted, symmetrically, with a small caveat ...

NTS: $C(f) \le 16(\log_2 \chi(f))^2$. [1]

Proof.

S

- If neither Alice nor Bob could find any M_i with low-enough degree, then they both know that every node i in $G := G_L \cap G_R$ for which $(x,y) \in M_i$ has degree $\geq (3\chi(f)/4)^2 = 9\chi(f)/16 > \chi(f)/2$.
- Let i,j both have degree $\geq \chi(f)/2$ in G. Then some node z is adjascent to i and j in G, by the Pigeonhole Principle. Hence $M_i \cap M_z \neq \emptyset$ and $M_j \cap M_z \neq \emptyset$. But the rectangles are monochromatic, hence, M_i and M_j are the same color. So Alice needs to find an M_i containing x and some $y \in Y$ whose degree in G is at least $\chi(f)/2$; and Bob's procedure is symmetric.

NTS: $C(f) \le 16(\log_2 \chi(f))^2$. [1]

Proof.

- In the worst case for each stage, the first participant sends "nothing found" (1 bit), the second participant sends some i ($\leq \log_2(\chi(f))$ bits), and the first participant replies with some j ($\leq \log_2(\chi(f))$ bits). So in the worst case each round requires $\leq 1 + 2\log_2(\chi(f))$ bits.
- The protocol ends after at most n rounds where $(3\chi(f)/4)^n \approx 1$, i.e., after $\log_{(4/3)}(\chi(f))$ rounds.
- So total communication complexity is $\leq \log_{(4/3)}(\chi(f)) * (1 + 2\log_2(\chi(f))).$

NTS: $C(f) \le 16(\log_2 \chi(f))^2$. [1]

Proof.

For $\chi(f) \ge 2$:

$$C(f) \leq \log_{(4/3)}(\chi(f)) * (1 + 2\log_2(\chi(f)))$$

$$= \frac{\log_2(\chi(f))}{\log_2(4/3)} * (1 + 2\log_2(\chi(f)))$$

$$< 2.5 * \log_2(\chi(f)) * (1 + 2\log_2(\chi(f)))$$

$$\leq 2.5 * \log_2(\chi(f)) * 3\log_2(\chi(f)))$$

$$= 7.5\log_2^2(\chi(f))$$

$$\leq 16\log_2^2(\chi(f))$$

I'm almost certainly missing a factor of 2, which would explain the choice of 16, -Max,

$$\frac{1}{2^n * 2^n} \Big| \sum_{a \in A, b \in B} (-1)^{M_{a,b}} \Big| \ge 1/K$$

Mathematicians like to name things.

Definition (Discrepency)

The *discrepency* of a rectangle $A \times B$ of M(f) is exactly the following.

Disc
$$(A \times B) = \frac{1}{2^n \times 2^n} |\sum_{a \in A, b \in B} (-1)^{M_{a,b}}|$$

The discrepency of M(f) is the max disc among its rectangles.

Communication Complexity

Now that we've named this thing, let's re-write our inequality.

 $\mathsf{Disc}(A \times B) \ge 1/K$

Now that we've named this thing, let's re-write our inequality.

$$\mathsf{Disc}(A \times B) \ge 1/K$$

Taking inverses:

$$\frac{1}{\mathsf{Disc}(A \times B)} \le K$$

Certainly $\chi(f) \le \chi(f)$, so supplanting $\chi(f)$ for K in the statement, we get:

Lemma (2-Party Discrepency Method)

$$\frac{1}{Disc(A \times B)} \le \chi(f)$$

Lemma (k-Party Discrepency Bound)

If $f: (\mathbb{B}^n)^k \to \mathbb{B}$ is a function, then $Disc(f) \leq (\mathcal{E}(f))^{1/2^k}$.

Proof sketch:

Proof.

Given any cylinder intersection and (n,k)-cube, what is the expectation / the image of the cube? What if we only consider points in the cylinder intersection? Derive a lower bound on $\mathcal{E}(f)$ like

$$\mathcal{E}(f) \ge E_{x_1,...,x_k} [f(x_1,...,x_k)(1 \text{ if } (x_1,...,x_k) \in C \text{ else } 0)]^{2k}$$

given a cylinder intersection C. Argue from the def. of the k-party discrepency that this gives a natural lower-bound $\mathcal{E}(f) \ge \operatorname{Disc}(f)^{2^k}$. But this implies $\operatorname{Disc}(f) \le (\mathcal{E}(f))^{1/2^k}$, and we're done.

Example (=)

Consider the equality function f(x, y) = 1 if x = y else 0.

- **Public Coin:** Alice sends the dot-product $\langle x, \text{coin} \rangle$ to Bob. Bob replies 1 if $\langle x, \text{coin} \rangle = \langle y, \text{coin} \rangle$ else 0. The chance of an erroneous "accept" is 1/2, so the protocol can be repeated three times (6 bits of communication) to get the desired result.
- **Private Coin:** Alice and Bob agree on a small set of possible random strings ahead of time. Alice sends her (privately random) choice from the set, using $\mathcal{O}(\log n)$ bits. Then the communication proceeds as if it were a public coin with that choice.
